TAKE-HOME ASSIGNMENT

Senior Fullstack Mobile + Backend Take-Home Assignment: KYC Onboarding App

Overview

Build a Flutter app (iOS + Android) that takes a user through an identity verification flow. Architecture, tooling, and technical decisions are yours to make and justify.

Backend is required. Build a real backend (any stack) that serves the API the app uses. Mocking the API is not accepted.

Features

1. **Authentication**: login, session handling, logout.
2. **Personal details**: collect and validate the user's identity information.
3. **Document capture**: capture an ID document (passport, national ID, or driving licence) with the camera.
4. **Selfie capture**: capture the user's face.
5. **Review & submit**: review everything, edit if needed, upload, submit.
6. **Verification status**: track the result, and handle rejection and resubmission requests.
7. **Resume**: an interrupted flow can be continued later.

Expectations

- Production-grade handling of sensitive data (PII, images, tokens).
- Resilient to unreliable networks and app lifecycle interruptions.
- Tested where it matters.

Deliverables

- Git repository with meaningful commit history.
- README: how to run, architecture and key decisions, security considerations, trade-offs, and what you would do with more time.
- Short screen recording of the full flow (no real identity documents).

- Backend source code and run instructions in the same repository.

Evaluation

Architecture, security and privacy, resilience, code quality, UX, testing, and clarity of communication.

AI tools are allowed; be ready to defend every decision in the follow-up interview. Where requirements are unclear, make an assumption and document it.

AI Development Workflow - Major Bonus

Building or applying a well-structured AI framework across the full software development lifecycle will be a significant advantage in the evaluation.

This is optional. Demonstrate a practical, repeatable workflow covering requirements analysis, architecture and planning, implementation, testing, code review, documentation, and delivery or maintenance.

Examples include reusable agent instructions, coding rules, prompt templates, task planning, review checkpoints, or AI-assisted CI workflows. You may build your own approach or adapt an existing framework.

If included, explain the workflow in your README and provide supporting repository artifacts or a short demo. Show where AI helped, how you validated its output, and how you retained ownership of quality and security.
